

Bot detection

Scores every session in layers and shows which layers fired.

TYPE	Detection service
VERDICTS	Allow to block
STATUS	Measured in the lab

100/100

runs challenged or blocked, for every attacker class A0 to A5, across our 3 own test sites

0.0%

of scripted humans flagged: all 5 sessions allowed, worst score 2

0.20 ms

p95 time to score a session, in process over 44 runs (mean 0.10 ms)

01

What it does

One score per session

Separate layers feed one fused score, so no single trick decides.

Shows why

Each result lists the layers that fired and what each layer alone would have done.

Keeps a dated ledger

Every drill that moves a number is logged. A4 and A5 went from missed on 1 October to challenged on 4 October.

02

How it works

1

Read in layers

Network, script, automation, behavior and agent layers are each checked alone.

2

Fuse into one score

The layers are combined. One layer alone can raise a challenge, never a block.

3

Act by level

The result is allow, slow, challenge or block.

03

Proof

Live drill of attacker classes A0 to A5 and 5 scripted humans on our own sites: every attacker class was challenged, every human was allowed.

METHOD

Simulated attackers against our own 3 test sites; A2 to A5 in real browsers

DATE

4 October 2026

SOURCE

fp-research scoreboard and arms-race ledger

Lab results on our own test sites with simulated attackers, not customer traffic. The 0.0% rests on 5 sessions; latency is in process.

OFFER

A pilot on your own sign-up or login form, with a written report at the end.
